

Logistic Regression

Classification

Email: Spam / Not Spam?

Online Transactions: Fraudulent (Yes / No)?

Tumor: Malignant / Benign?

$y \in \{0,1\}$

- 0: Negative Class (benign tumor)
- 1: Positive Class (malignant tumor)

→ **Binary classification**

Note: $y \in \{0,1,2,3, \dots\}$: **Multi-class classification** is an extension of binary classification

Classification Based on Probability

Instead of just predicting the class, give the probability of the instance being that class, i.e., learn $p(y|x)$

Recall that:

$$0 \leq p(\text{event}) \leq 1$$

$$p(\text{event}) + p(\neg\text{event}) = 1$$

Interpretation of Hypothesis Output

$$h_{\theta}(\mathbf{x}) = \text{estimated } p(y = 1 \mid \mathbf{x}; \theta)$$

Example: Cancer diagnosis from tumor size

$$\mathbf{x} = \begin{bmatrix} x_0 \\ x_1 \end{bmatrix} = \begin{bmatrix} 1 \\ \text{tumorSize} \end{bmatrix}$$

$$h_{\theta}(\mathbf{x}) = 0.7$$

→ Tell patient that 70% chance of tumor being malignant

Note that: $p(y = 0 \mid \mathbf{x}; \theta) + p(y = 1 \mid \mathbf{x}; \theta) = 1$

Therefore, $p(y = 0 \mid \mathbf{x}; \theta) = 1 - p(y = 1 \mid \mathbf{x}; \theta)$

Logistic Regression

$$h_{\theta}(x) = g(\theta^T x)$$

$$g(z) = \frac{1}{1 + e^{-z}}$$

$\theta^T x$ should be large negative values for negative instances

$\theta^T x$ should be large positive values for positive instances

- Assume a threshold and...
 - Predict $y = 1$ if $h_{\theta}(x) \geq 0.5$
 - Predict $y = 0$ if $h_{\theta}(x) < 0.5$

Classification

Classification: $y=0$ or $y=1$, but $h_{\theta}(x)$ can be >1 or <0

Logistic regression: $0 \leq h_{\theta}(x) \leq 1$

→ use **Sigmoid / Logistic Function**

Logistic Regression Model

We want our classifier to output values between 0 and 1

- When using linear regression we did $h_{\theta}(x) = \theta^T x$
- For classification hypothesis representation we do $h_{\theta}(x) = g(\theta^T x)$ where $g(z) = \frac{1}{1+e^{-z}}$ is a Sigmoid (or Logistic) function.

$$\text{Thus } h_{\theta}(x) = \frac{1}{1+e^{-\theta^T x}}$$

Logistic Regression

- Takes a probabilistic approach to learning discriminative functions (i.e., a classifier)
- $h_{\theta}(x)$ should give $p(y = 1 \mid x; \theta)$
 - Want $0 \leq h_{\theta}(x) \leq 1$
- Logistic regression model:

$$h_{\theta}(x) = g(\theta^T x)$$

$$g(z) = \frac{1}{1 + e^{-z}}$$

$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}}$$

Logistic Regression

Training
set:

$$\{(x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \dots, (x^{(m)}, y^{(m)})\}$$

m examples

$$x \in \begin{bmatrix} x_0 \\ x_1 \\ \dots \\ x_n \end{bmatrix} \mathbb{R}^{n+1}$$

$$\underline{x_0 = 1}, \underline{y \in \{0, 1\}}$$

$$\left[h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}} \right]$$

How to choose parameters θ ?

MSE is a non-convex loss function in Logistic Regression

Recall the MSE loss function of Linear regression:

$$J(\theta) = \frac{1}{2n} \sum_{i=1}^n (h_{\theta}(x^{(i)}) - y^{(i)})^2$$

In case of Logistic Regression, $h_{\theta}(x) = \frac{1}{1+e^{-\theta^T x}}$, the MSE loss function is **non-convex** \rightarrow Easy to be trapped at a local minimum \rightarrow Need to find a **convex** loss function for Logistic Regression.

A convex loss function for Logistic Regression

Loss function of Logistic Regression:

$$J(\theta) = \begin{cases} -\log(h_{\theta}(x)) & \text{if } y = 1 \\ -\log(1 - h_{\theta}(x)) & \text{if } y = 0 \end{cases}$$

This is the penalty that the algorithm applies to prediction output during the training process.

Intuition of Logistic Regression loss function

Loss function of Logistic Regression:

$$J(\theta) = \begin{cases} -\log(h_{\theta}(x)) & \text{if } y = 1 \\ -\log(1 - (h_{\theta}(x))) & \text{if } y = 0 \end{cases}$$

if $y = 1$

if $y = 1$:

- $J(\theta) = 0$ if prediction is correct.
- As $h_{\theta}(x) \rightarrow 0$, $J(\theta) \rightarrow \infty$.
- This loss function captures intuition that larger mistakes should get larger penalties. Example: predict $h_{\theta}(x) = 0$, but $y = 1$.

Intuition of Logistic Regression loss function

Loss function of Logistic Regression:

$$J(\theta) = \begin{cases} -\log(h_{\theta}(x)) & \text{if } y = 1 \\ -\log(1 - (h_{\theta}(x))) & \text{if } y = 0 \end{cases}$$

if $y = 0$:

- $J(\theta) = 0$ if prediction is correct.
- As $h_{\theta}(x) \rightarrow 1, J(\theta) \rightarrow \infty$.
- This loss function captures intuition that larger mistakes should get larger penalties. Example: predict $h_{\theta}(x) = 1$, but $y = 0$.

Cost Function Simplification

$$J(\theta) = \frac{1}{m} \sum_{i=1}^m \text{cost} \left(h_{\theta}(x^{(i)}), y^{(i)} \right)$$

$$\text{cost} (h_{\theta}(\mathbf{x}), y) = \begin{cases} -\log(h_{\theta}(\mathbf{x})) & \text{if } y = 1 \\ -\log(1 - h_{\theta}(\mathbf{x})) & \text{if } y = 0 \end{cases}$$

Note: $y = 0$ or $y = 1$ always

How to rewrite (simplify) the cost function $J(\theta)$?

Cost Function Simplification

$$J(\theta) = \frac{1}{m} \sum_{i=1}^m \text{cost} \left(h_{\theta}(x^{(i)}), y^{(i)} \right)$$

$$\text{cost} (h_{\theta}(\mathbf{x}), y) = \begin{cases} -\log(h_{\theta}(\mathbf{x})) & \text{if } y = 1 \\ -\log(1 - h_{\theta}(\mathbf{x})) & \text{if } y = 0 \end{cases}$$

Note: $y = 0$ or $y = 1$ always

$$\text{cost} (h_{\theta}(x), y) = -y \log(h_{\theta}(x)) - (1 - y) \log(1 - h_{\theta}(x))$$

$$\text{If } y = 1 : \text{cost} (h_{\theta}(x), y) = -\log(h_{\theta}(x))$$

$$\text{If } y = 0 : \text{cost} (h_{\theta}(x), y) = -\log(1 - h_{\theta}(x))$$

Logistic Regression Cost Function

$$\begin{aligned} J(\theta) &= \frac{1}{m} \sum_{i=1}^m \text{cost} \left(h_{\theta}(x^{(i)}), y^{(i)} \right) \\ &= -\frac{1}{m} \left[\sum_{i=1}^m y^{(i)} \log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)})) \right] \end{aligned}$$

To fit parameters θ :

Compute $\min_{\theta} J(\theta) \rightarrow$ Get θ

To make prediction given new x :

$$\text{Output } h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}} = p(y = 1|x, \theta)$$

Gradient Descent

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m y^{(i)} \log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)})) \right]$$

Want $\min_{\theta} J(\theta)$:

Repeat {

$$\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta)$$

}

where
$$\frac{\partial}{\partial \theta_j} J(\theta) = \frac{1}{m} \sum_{i=1}^m \left(h_{\theta}(x^{(i)}) - y^{(i)} \right) x_j^{(i)}$$

Gradient Descent

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m y^{(i)} \log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)})) \right]$$

Want $\min_{\theta} J(\theta)$:

Repeat {

$$\theta_j := \theta_j - \alpha \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

}

This looks IDENTICAL to linear regression!!!

- Ignoring the $1/m$ constant
- However, the form of the model is very different:

$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^T x}}$$

Gradient Descent with Regularization

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m y^{(i)} \log(h_{\theta}(x^{(i)})) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)})) \right]$$

$$J_{regularized}(\theta) = J(\theta) + \lambda \sum_{j=1}^d \theta_j^2 = J(\theta) + \lambda \|\theta_{[1:d]}\|_2^2$$

Want $\min_{\theta} J(\theta)$:

Repeat {

$$\theta_j := \theta_j - \alpha \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)}) x_j^{(i)} - \lambda \theta_j$$

}

Multi-class classification

Binary classification:

Multi-class classification:

Disease diagnosis: healthy / cold / flu / pneumonia

Object classification: desk / chair / monitor / bookcase

One-vs-all (one-vs rest)

Take the max-probability class among all logistic regression classifiers.
Extra reading: **softmax regression**.

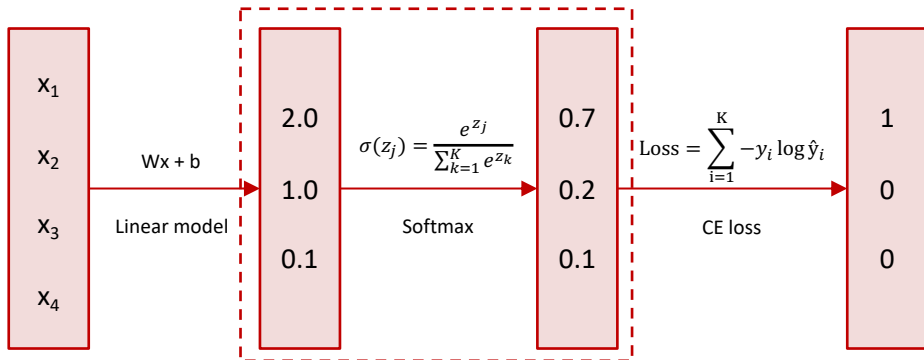

Softmax regression

Softmax regression (or multinomial logistic regression) is a generalization of logistic regression to the case where we want to handle multiple classes.

Softmax regression

Softmax regression (or multinomial logistic regression) is a generalization of logistic regression to the case where we want to handle multiple classes.

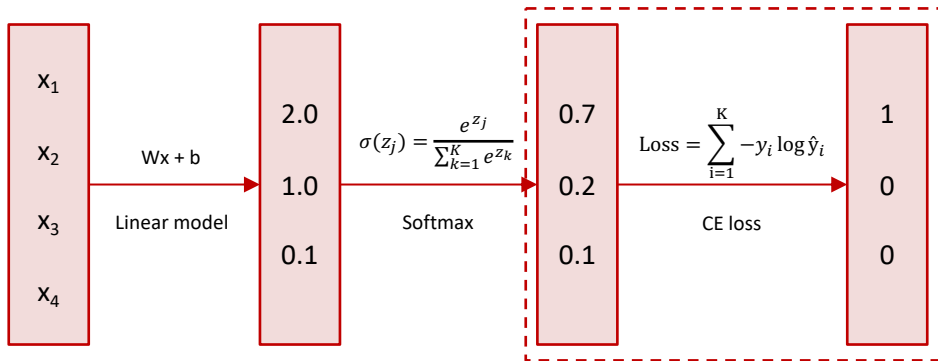

$$\sigma(2.0) = \frac{e^{2.0}}{e^{2.0} + e^{1.0} + e^{0.1}} = 0.7$$

$$\sigma(0.1) = \frac{e^{0.1}}{e^{2.0} + e^{1.0} + e^{0.1}} = 0.1$$

$$\sigma(1.0) = \frac{e^{1.0}}{e^{2.0} + e^{1.0} + e^{0.1}} = 0.2$$

Softmax regression

Softmax regression (or multinomial logistic regression) is a generalization of logistic regression to the case where we want to handle multiple classes.

$$\text{Loss} = -1 \times \log_2 0.7 - 0 \times \log_2 0.2 - 0 \times \log_2 0.1 = 0.51$$

Evaluation metrics

General method: calculate the **difference** between ground-truth labels and model predictions.

Example: testing 165 emails in a spam/non-spam classification problem.

	Prediction YES	Prediction NO
Actual YES	100	5
Actual NO	10	50

Evaluation metrics

Example: testing 165 emails in a spam/non-spam classification problem.

	Prediction YES	Prediction NO
Actual YES	100	5
Actual NO	10	50

- Precision = $100/(100+10) \sim 91\%$: how many predicted items are relevant.
- Recall = $100/(100+5) \sim 95\%$: how many relevant items are predicted.

Evaluation metrics

Example: testing 165 emails in a spam/non-spam classification problem.

	Prediction YES	Prediction NO
Actual YES	True Positive TP	False Negative FN
Actual NO	False Positive FP	True Negative TN

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall}$$

Summary

Binary Classification

Decision Boundary

Logistic Regression

- Sigmoid function
- Cost Function
- Optimization
- Regularization

Multi-class (Multinomial Classification)

- One-vs-all
- Softmax regression
